## 1. Introduction

Muqarnas is a decorative design element widely used in traditional Islamic architecture. Muqarnas elements are known for their complex geometries and artistic textures. With the rise of digital design, new possibilities have emerged for the parametric modeling of muqarnas designs. There are many studies aimed at deciphering the geometric and topological properties of muqarnas (Sakkal 1988; Özdural 1990; Büyükdığın 2001; Yaghan 2003, Güzelce 2021).

Muqarnas is a three-dimensional geometric form with a structure that narrows from bottom to top and can be designed in many different shapes and sizes. Today, muqarnas design and production can be achieved using digital technologies and computational design tools.

This study explains how the muqarnas design can be created parametrically using Rhino and Grasshopper programs, and shows that it is possible to reinterpret the traditional muqarnas in digital design.

## 2. Parametric Muqarnas design with Rhino-grasshopper

Rhino-Grasshopper programs are one of the most effective tools that can be used for the parametric design of muqarnas. These programs allow designers to determine the size, shape, complexity, and symmetry of the muqarnas by entering parameters and easily changing these parameters.

“Traditional geometry modeling tools are mostly tools that work with the logic of “design and change” and enable the designer to create results created by free-form forms and simple geometries” (Kaçmaz, 2019). Professor Robert Woodbury defines Parametric modeling tools as follows: "Parametric modeling tools are tools that allow the designer to model the relationships between design parameters and create design alternatives through the algorithm he establishes." (Woodbury 2010).

The possibility of reinterpreting the traditional muqarnas in digital design with the Rhino-Grasshopper program can be listed as follows:

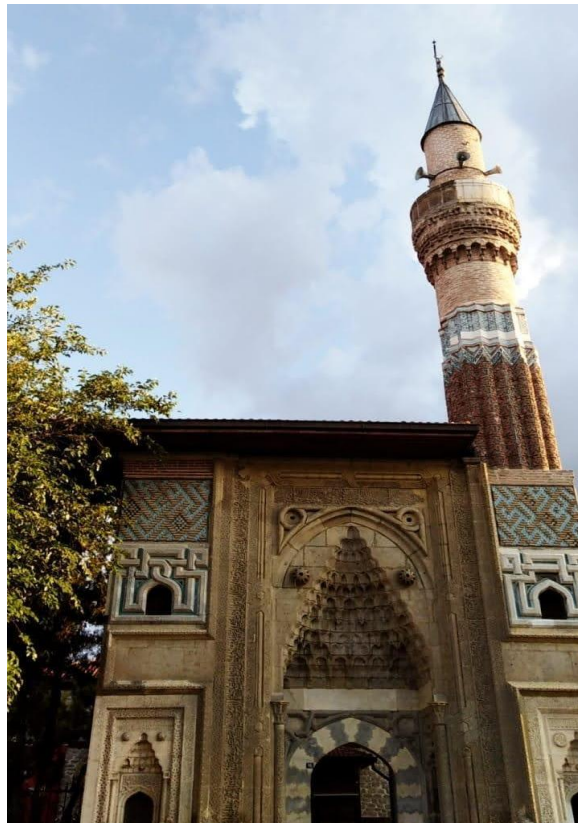

1. *By promoting an innovative approach to architecture, it also allows the reinterpretation of traditional architectural elements in digital design and enables their integration into modern designs.*
2. *Of muqarnas to be modeled and redesigned using three-dimensional and multi-dimensional planes.*
3. *Muqarnas in a digital environment by using parametric input and output and entering parameters such as the size, shape, and complexity of the muqarnas they want.*
4. *It helps designers create new and original designs using traditional shapes of muqarnas.*
5. *It allows easy modification and development of the design.*

Seljuk period mosques in Konya City offer the most important examples of muqarnas art. Designing the muqarnas in these mosques parametrically using Rhino-

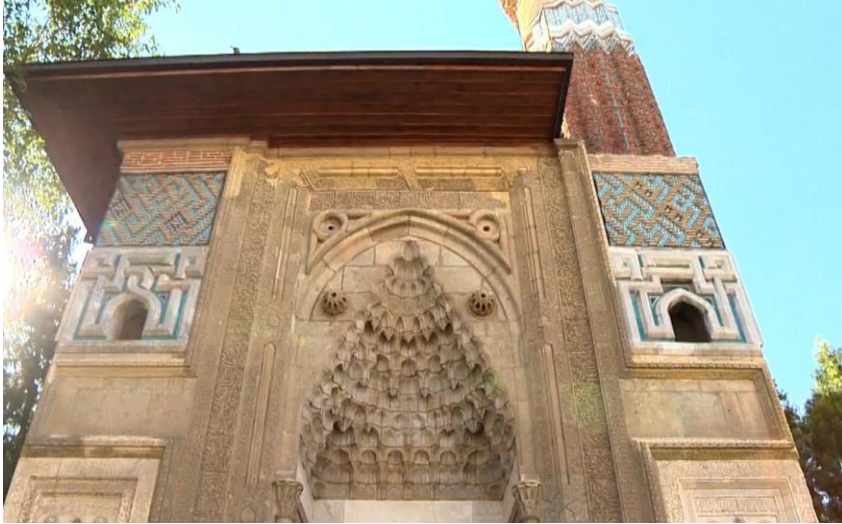

Grasshopper is important in terms of understanding the existing traditional methods and archiving the designs by digitalizing them, as well as creating different prototypes of new designs inspired by traditional designs.

Of the muqarnas in the historical mosques in Konya, it is observed that they have a visually noticeable symmetrical design. The rhino-Grasshopper program allows controlling and customizing these designs with parameters.

The design of the muqarnas is created algorithmically in Grasshopper. First, it is essential to draw the general geometric form of the muqarnas as a plan in digital design. With developing technology and transitions between programs, designs can be easily transferred to each other in the digital environment. In this study, the current version of the muqarnas plan used in the crown gate was drawn in two dimensions in the AutoCAD program, based on the muqarnas sample used in the Konya Sahip Ata Mosque (Figure 1-3). Afterward, the details, layers, and external appearance of the muqarnas were based on its current state after the restoration. By the principles of the study, these details were computationally designed and optimized in the Rhino-Grasshopper program by transferring them to the program in the same extension.

**Figure 1:** Facade of Konya Sahip Ata Mosque (Personal archive)

**Figure 2.** Muqarnas and crown gate decorations of Konya Sahip Ata Mosque (Personal archive)

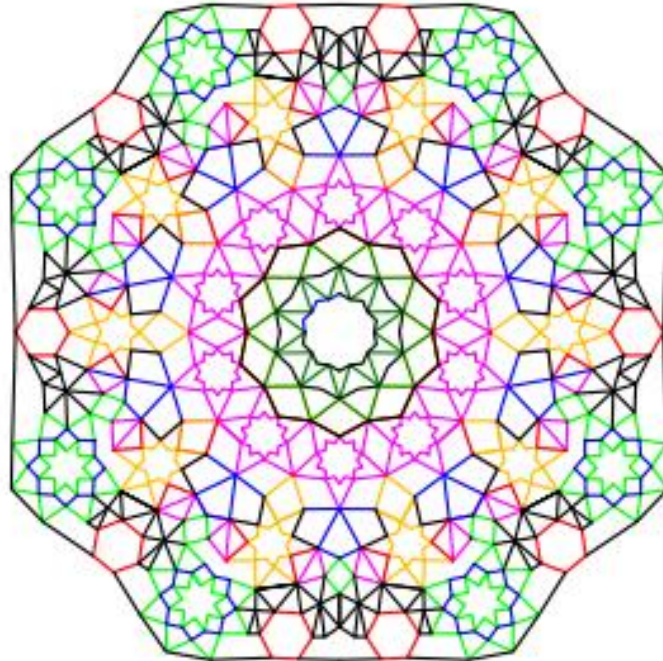

### *2.1. Muqarnas design stages with Rhino-grasshopper*

Symmetry is an important factor in muqarnas design. In this context, Rhino-Grasshopper is a very convenient program to use. The program offers various tools to ensure symmetry. In this program, appropriate parameters can be set to determine the symmetry of the muqarnas. At the same time, Rhino-Grasshopper's symmetry tool automatically retrieves the symmetry of the design being worked on.

#### *2.1.1. Symmetry or Asymmetry of Design in Grasshopper*

The Rhino-Grasshopper program provides a set of algorithms for creating symmetrical or asymmetrical designs. Here are some examples:

**1. Symmetrical Design:** To create a symmetrical design, you start by determining the symmetry plane. This symmetry plane is defined using the Design → Vectors → Plane command. Using this command, a symmetrically repeating pattern can be created in the design around the symmetry plane. For example, to create a symmetrical shape, you can rotate a series of lines around a specific plane of symmetry.

**Figure 3:** *Konya Sahip Ata Mosque Muqarnas dwg plan*

**2. Asymmetrical Design:** Random elements can be added to your design to create an asymmetrical design. For this, the Random command is used to generate random coordinates. Then, using the Design → Geometry → Line command, arbitrary lines or curves can be created. To make the design asymmetrical, these random elements can be placed in different sizes and positions.

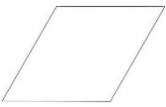

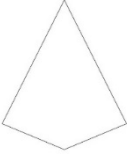

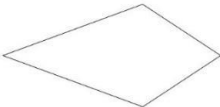

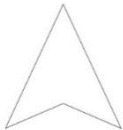

**3. Symmetrical-Asymmetrical Design:** The Rhino-Grasshopper program can also create designs consisting of a combination of symmetrical and asymmetrical elements. These designs can start with symmetrical elements around the plane of symmetry and then be completed with random elements. This approach allows to combine of both orderliness and convenience in design.

The above approaches include many different ways to create symmetrical or asymmetrical designs in Rhino-Grasshopper. Many different algorithms can be used to ensure the symmetry or asymmetry of the design. Determining the best approach to your design depends on the design goals.

Of muqarnas generally occurs by drawing plane projections (Harmsen 2006). These plane projections can be thought of as muqarnas, simple patterns that are not connected. In these cases, the arrangement of muqarnas elements is mostly symmetrical (Harmsen 2006).

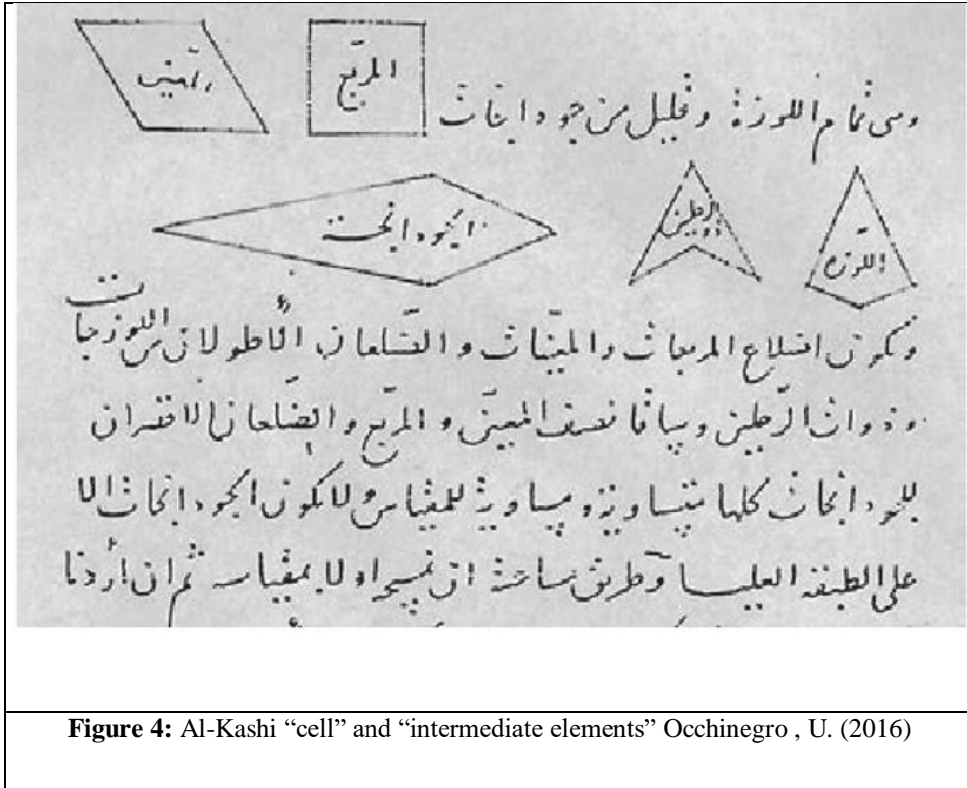

Another distinction used by Al-Kashi in many fields is the assumption of "cell" and "intermediate elements" in muqarnas studies. The top of each cell contains the "roofs" and the vertical surfaces contain the "surfaces." Filling elements complete the compositions (Occhinegro 2016). Looking at Kashi's description, it is clear that he sees muqarnas as unique. Its uniqueness is that it consists of blocks systematically arranged in step-like rows, written by Lisa Golombek. *Timurid Architecture of Iran and In Turan's book*, Every cell is a three-dimensional shape (Golombek 1991). He transferred it as a two-dimensional drawable drawn by the boundaries of its two subplanes. According to Kashi, it shows the five basic shapes that combine the lower and upper.

These are as follows:

1. <i>Square</i>	2. <i>Rhombus</i>	3. <i>Almond-shaped diamond or deltoid</i>
		
4. <i>Long lozenge ("barleycorn")</i>	5. <i>Two-ended figure (literally, bipedal, lozenge-shaped at one end)</i>	
		

### 2.1.2. *Interpretation of Muqarnas Parametric Design with Rhino-Grasshopper*

The first step is to determine the basic geometry of the muqarnas. The parametric design of muqarnas is accomplished through the use of some parameters. These include the dimensions, height, angles, and details of the muqarnas. By entering a set of parameters in Rhino-Grasshopper, the algorithm is created and the shape and dimensions of the muqarnas are automatically created based on the design parameters.

Muqarnas Design allows designers to easily adjust the sizes and shapes they want. Rhino-Grasshopper can also be used to easily create more complex elements of the muqarnas design. Some muqarnas design parameters are:

- *Size:* Designers can specify the size of the muqarnas. This may include dimensions such as the width, height, and depth of the muqarnas.
- *Angles:* Muqarnas's design is created by using certain angles. Designers can create different designs by adjusting the angles of the muqarnas.
- *Detail:* Details of the muqarnas design can be adjusted according to the wishes of the designers. Details can make the muqarnas more complex or simpler.

Muqarnas using three-dimensional and multi-dimensional planes using the Rhino-Grasshopper plug-in are as follows:

1. *First, the design of the muqarnas must be created in 2D using the Rhino program. For this purpose, a base drawing is prepared in the Rhino program to create the design of the muqarnas. In this base drawing, the general contour line of the muqarnas is determined and the geometric shapes typically used for traditional muqarnas design are created.*

2. *Then, the parameters of the 2D design of the muqarnas are entered using the Rhino-Grasshopper plugin. To do this, a problem appropriate to the plane and geometric features of the 2D design must be created and commands must be entered.*
3. *Some of the muqarnas can be determined with parametric inputs. These inputs are used to define the characteristics of muqarnas.*
4. *According to the specified parameters, the 3D structure of the muqarnas can be changed on the Grasshopper plugin and different versions of the design can be created. These are all defined parameters. Thus, digital modeling of the muqarnas begins using the algorithm entered in Grasshopper. The algorithm creates the geometric forms of the muqarnas according to the entered parameters and is displayed on the Rhino screen.*
5. *Various tools can be used to examine and visualize the 3D model of the digitally designed muqarnas created in the Rhino program. If the designer deems it necessary, he can use various settings in the Rhino program to view and render various angles of the model.*
6. *When it is desired to make any changes in the design of the muqarnas, it is sufficient to readjust the parametric inputs and the algorithm automatically creates the new muqarnas shape. This provides flexibility and speed in the design process.*
7. *When the design is completed, the digitally designed muqarnas file can be converted to various file formats in the Rhino program and transferred to other programs or devices for use in the production phase.*

With the completion of these stages, the designer can use the Rhino-Grasshopper program to create a digital design that models the complex geometric forms of the muqarnas using three-dimensional and multi-dimensional planes.

#### *2.1.2.1. Grasshopper and Parameter*

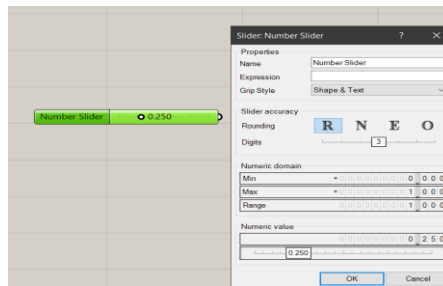

In Grasshopper, parameters are added primarily from the panel, where many parametrically adjustable components are available. You can add a parameter by following these steps:

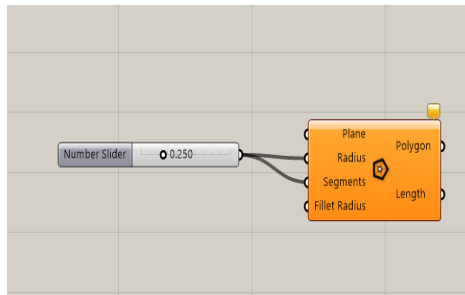

4. **Select the component and set parameters in the " Properties " panel.**  
For example, parameters such as "Minimum", "Maximum" and "Step Size" can be adjusted depending on the number slider (Figure 8).
5. **Connect this parameter to other components you want to use in your design by creating connections (Figure 9).**

By completing these steps, you will create a component such as a number slider that will allow you to play with the parameters in your design. This can be done quickly by using Grasshopper's parametric design feature, testing and optimizing your design with different parameter values.

**Figure 8:** Grasshopper number slider number screenshot from the slider's properties tab

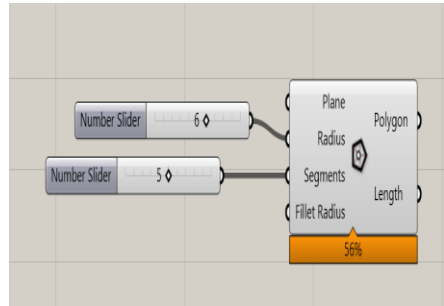

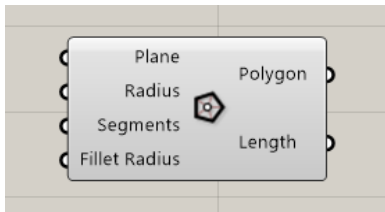

**Figure 9:** Grasshopper number screenshot of connecting the slider and polygon component

Grasshopper the following steps are followed to create a polygon from the basic geometric structure of muqarnas:

1. A new identifier (component) is added in Grasshopper. To do this, go to the " Params " tab and select the " Polygon " identifier from the " Geometry " submenu (Figure 10).

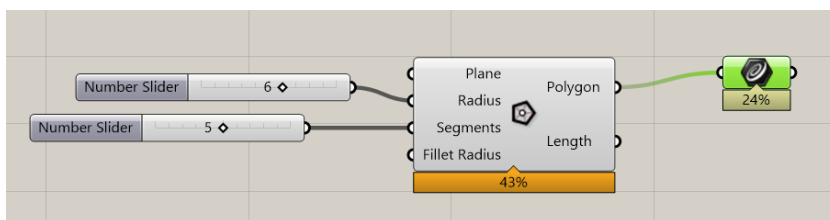

2. The polygon identifier placed on the screen is double-clicked to make it clickable in the " Vertices " entry.
3. In the window that opens, determine the number of corners of the polygon and click the "OK" button.
4. The "Radius" parameter is used to adjust the size of the polygon. (Figure 11)

**Figure 10:** Screenshot of the Grasshopper polygon component

**Figure 11:** Using the "Radius" parameter

5. To see the created polygon on the screen, the " Curve " identifier is added. The output from the Polygon descriptor is connected to the input of the "Curve" descriptor ( Figure 12).

**Figure 12:** Connecting the " Curve " component to " Polygon "

6. To see the polygon on the screen, connect the output of the " Curve " descriptor to the "Preview" descriptor.

After completing these steps, a polygon is created in Grasshopper. By changing parameters such as number of vertices and size, polygons of different shapes can be created.

### *2.1.2.2. Defining the parameter entered in the algorithm in Grasshopper*

Rhino-Grasshopper, algorithms are often used for data processing and transformation. Therefore, once a parameter is input, the algorithm can be used to process or transform that input in a specific way. Various tools and components are used to perform this operation of the algorithm.

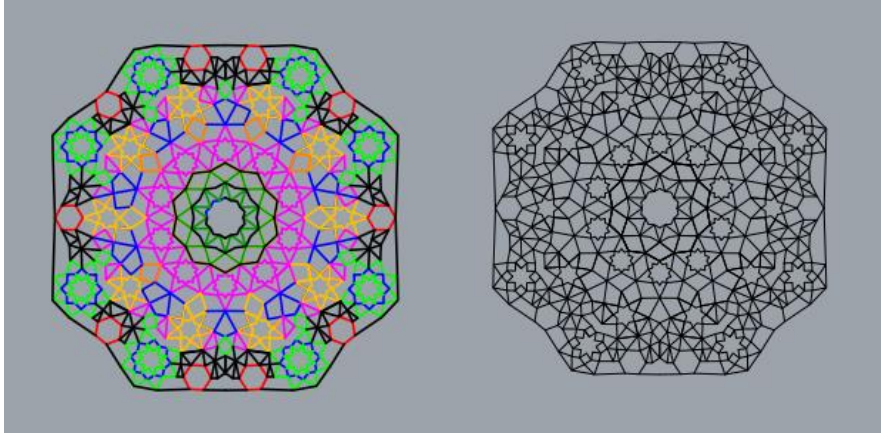

For example, to get a numeric parameter use " Number Slider " component is used. This component provides a slider or value entry field for the parameter. The entered numerical parameter is stored as a data tree in Grasshopper for use in other components. This data tree allows you to transfer the parameter you enter to other components for use in different components.

On the other hand, for a text parameter, the " Text Panel " or " String " component is used. These components provide a text field for the text parameter. The text parameter you enter is also stored as a data tree and can be passed as data for use in other components.

Entering a parameter in Rhino-Grasshopper is used to process or transform this parameter. To do this, it is necessary to select the appropriate components and interconnect them with connections to process or transform the parameter you entered. Thus, the algorithm receives the data needed to process or transform the entered parameter. The muqarnas, it is sufficient to readjust the parametric inputs and through which steps does the algorithm automatically create the new muqarnas shape? The Rhino-Grasshopper program automatically detects any changes made to the design parameters and creates a new muqarnas shape accordingly. This process is carried out thanks to the parametric design features of the program. That is, readjusting the parametric inputs triggers a rerun of the algorithm and a new muqarnas shape is created. Any desired changes can be made easily in this design and the algorithm automatically creates the new shape, speeding up the process and allowing the design to be improved.

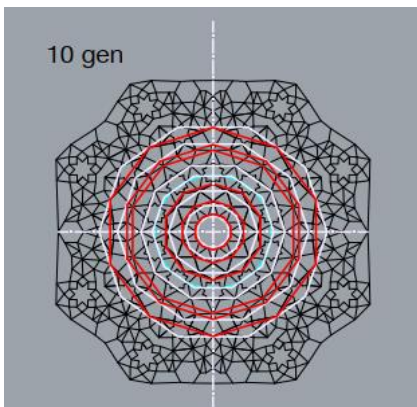

The following steps can be followed to design muqarnas models with multiple layers or cross shapes:

1. First of all, the necessary geometric forms are created in Rhino-Grasshopper to determine the layers or cross shapes of the muqarnas. These forms can be designed on the plan plane and can also be converted to 3D after processing (Figure 13).

**Figure 13:** Plan scheme in which the geometries of the muqarnas of the Sahip Ata mosque are determined.

2. Various fasteners are used in Grasshopper to connect layers or cross shapes together. These are elements used to join different layers or cross shapes of muqarnas (Figure 14).
3. In Rhino-Grasshopper, several parameters can be added to control the entire design. For example, we can give an example of adding parameters to control parameters such as the height, width, or angle of the muqarnas.
4. Then be viewed in Rhino to review the design and make any changes.
5. In Rhino-Grasshopper to optimize the design. For example, using some algorithms to ensure the symmetry or asymmetry of the design. (Figure 15)

**Figure 14:** Layers of geometries of the muqarnas of the Sahip Ata mosque

**Figure 15:** Axes of the geometries of the muqarnas of the Sahip Ata mosque

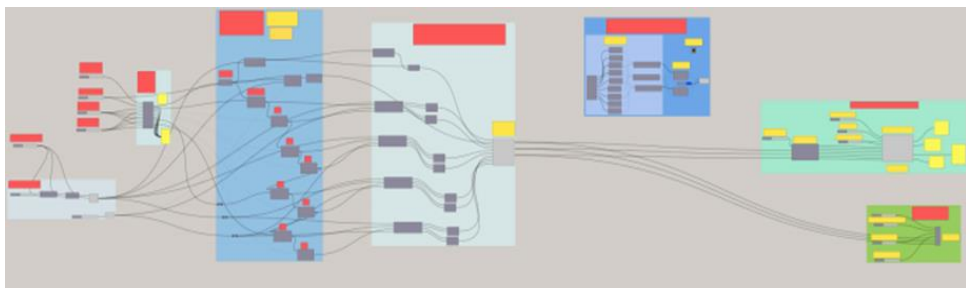

6. Once the design is complete, Rhino can create the files needed for production.

The muqarnas design becomes more complex, the Rhino-Grasshopper program allows for more detailed and precise control of the design. Additionally, optimizing the design using algorithms can be very useful in situations where the design becomes more complex.

The following steps can be followed to enter a parameter in Rhino-Grasshopper and to process or convert this parameter (Figure 16):

1. *Select parameters:* For example, the side length of a polygon, the radius of a circle, etc.
2. *Manipulate parameters:* Appropriate mathematical operations are used to process the selected parameters. Commonly used mathematical operations in Rhino-Grasshopper include addition, subtraction, multiplication, division, square root, exponentiation, etc. takes place. These operations can be performed using Rhino-Grasshopper 's mathematical tools.
3. *Convert parameters:* Processed parameters can be converted into different data types that can be used in your design. For example, you can convert a number value to a string or a point coordinate.
4. *Use parameters:* By using the converted parameters in other components in Rhino-Grasshopper, they can be used in different parts of your design. These parameters are used to create geometry in your design, analyze data, or generate outputs.

In Rhino-Grasshopper using parameters manipulation and transformation steps. This allows designers to easily control parameters in different parts of the design (Figure 17).

**Figure 17:** Grasshopper view of the work worked on in the Grasshopper program (Personal archive)

This means that it offers a new method for the interactive modeling of muqarnas, and according to sources, the layered structure floor layouts are used as a guide for the modeling workflow, automatically renewing new forms and creating new layers while renewing (Occhinegro 2016).

The creation of 3D Seljuk muqarnas using Rhino-Grasshopper is achieved in conjunction with the 3D modeling capabilities of the Rhino program. The following steps are a general guide to creating a Seljuk muqarnas using Rhino-Grasshopper (Figure 18):

1. ***Create a drawing surface in Rhino:*** Seljuk muqarnas are generally drawn on flat surfaces, so you first need to create a drawing surface in Rhino. The surface should be scaled according to the size and shape of the muqarnas.
2. ***Open Grasshopper:*** Grasshopper is used as a plugin in Rhino. It can be opened by running the " Grasshopper " command in Rhino.
3. ***Of muqarnas:*** *The basic geometric shapes of Seljuk muqarnas are mostly semicircles, arches, arcs, and curves. You can create these shapes in Rhino or using Grasshopper's " Curve " components.*

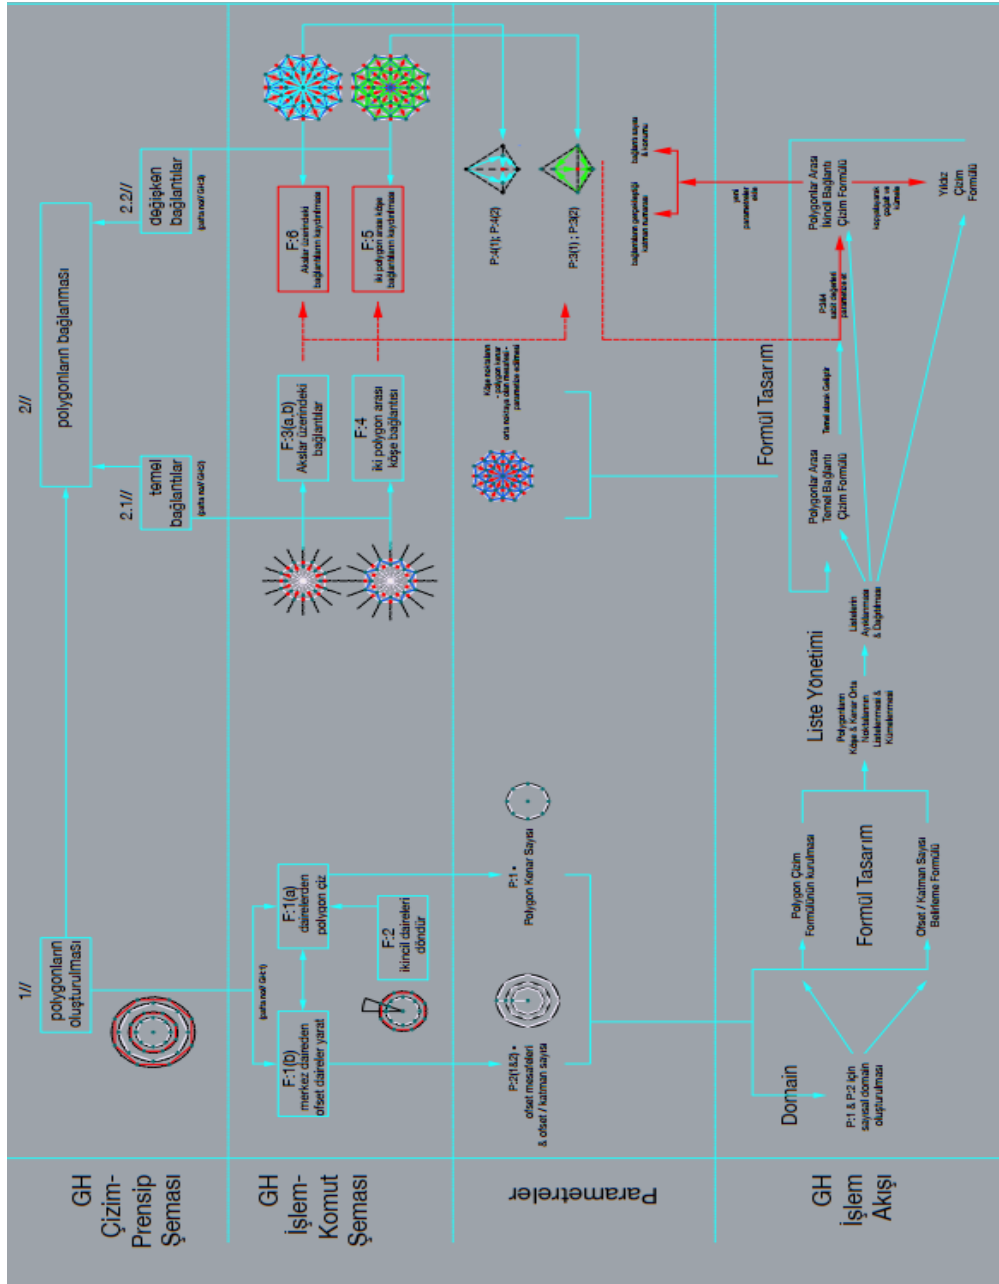

Figure 16: General process and road map of the work on the Grasshopper program

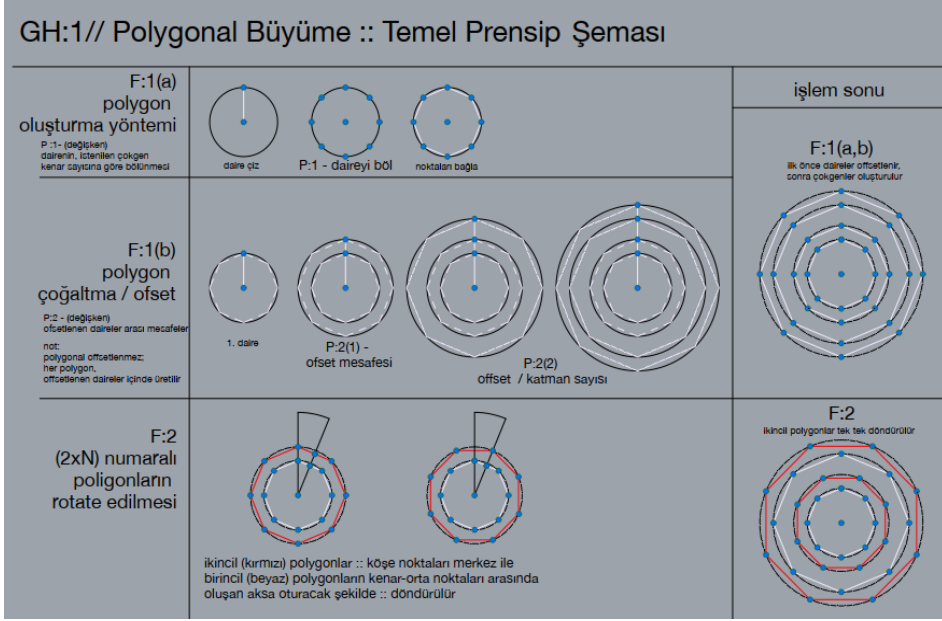

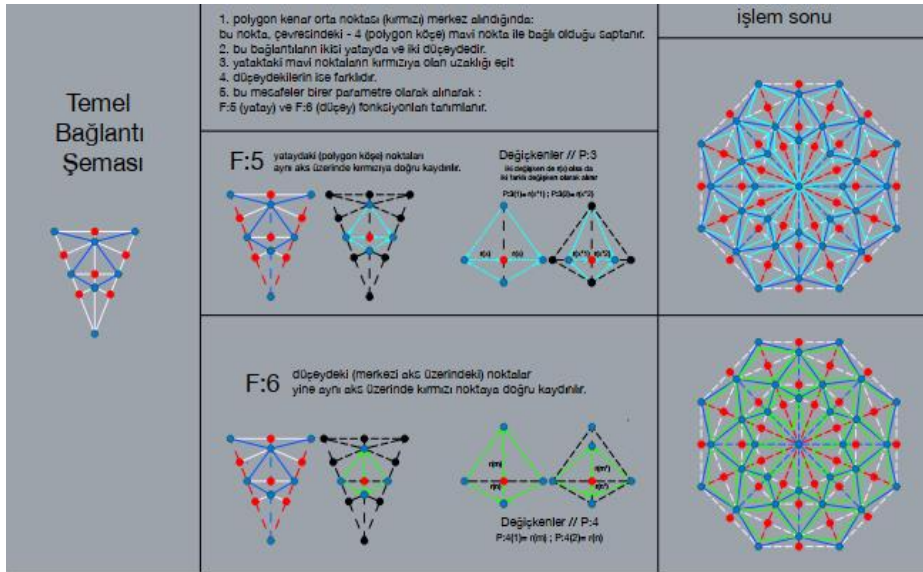

Figure 18: Basic principle diagram of geometry discussed in Grasshopper

4. **Combine geometric shapes:** You can create a basic Seljuk muqarnas model by combining geometric shapes. This step can be accomplished using Rhino's "Join" command.
5. **Duplicate pattern:** Seljuk muqarnas often contain repeating patterns. You can do this using Grasshopper's "Array" component.
6. **Create more complex patterns:** Seljuk muqarnas often consist of many layers, and each layer is a combination of different geometric shapes. Using Grasshopper, you can create more complex muqarnas models by defining the geometry and relationships of each layer.
7. **Finalize:** The last step is to add the details of the muqarnas model, adjust its size, and make the necessary edits. You can make changes as needed using other tools, such as Rhino's "Boolean" command.

The above steps are a general guide to creating Seljuk muqarnas using Grasshopper. This process may be more detailed or take different forms depending on the complexity and scale of the design (Figure 19).

**Figure 19:** Determination of points and symmetry and view of point coordinates in the basic connection diagram of the main muqarnas of the study on the Grasshopper program

Symmetry and partially repeated geometry make it difficult to model the muqarnas and solve the problem easily. It makes it harder to overcome your problem. Thus, by creating advanced elements and patterns of traditional muqarnas with challenging equations and where modern digital design methods and digital algorithms are unclear, digital modeling can facilitate the discovery of architectural style with a modern method in deciphering Islamic art, including muqarnas (Güzelci and Alaçam 2019).

### 3. Conclusion

With the mentioned methods, it becomes possible to digitally design the muqarnas. This approach offers an opportunity to reinterpret traditional architectural elements in digital design and use them in modern designs. The Rhino-Grasshopper program allows designers to have more flexibility and control in the design process, as designers can easily explore different shapes and sizes of muqarnas by changing the parameters. While this work encourages an innovative approach in architecture, it also enables the integration of traditional architectural elements into modern designs.

In conclusion, Rhino-Grasshopper is a very effective tool in the digital parametric design of muqarnas. Using these programs, designers can create complex geometric forms and control the size, shape, symmetry, and details of the muqarnas. Additionally, parametric redesign of muqarnas in historical mosques will also help digitally preserve this art.

## ÖZET

**Muqarnas'ın rhino-Grasshopper programı kullanılarak dijital tasarımda geleneksel bir mimari unsur olarak yeniden yorumlanması**

**Yasemin TURAN**

**Ankara Yıldırım Beyazıt Üniversitesi, Türkiye**

**İhsan TOKTAŞ**

**Ankara Yıldırım Beyazıt Üniversitesi, Türkiye**

Mukarnaslar İslam mimarisinde yaygın olarak, bulunan geleneksel mimari unsurlardır. Binalara ve diğer yapılara görsel ilgi, derinlik kazandırmak amacıyla kullanılan bu üç boyutlu dekoratif unsurlar, kubbe ve tonoz süslemelerinde yaygın olarak kullanılmıştır. Mukarnaslar, İslami geometrik desenlerin üst-üste istiflenmesiyle oluşturulan üç boyutlu, karmaşık geometrik şekillerdir. Mukarnas geleneksel teknikler üzerine kullanılmış, oyma ve kalıplama gibi aşamalarla, zaman alıcı ve zahmet talep eden bir iştir. Günümüzde dijital ortamda çeşitli algoritmalar ve parametrik tasarım yöntemleri kullanılarak karmaşık mukarnasların hızlı ve kolay bir şekilde oluşturulması, temel modellerden yeni değişken modellere- Rhino-Grasshopper gibi tasarım araçların oluşturulması mümkün hale gelmiştir.

Bu çalışmada Rhino-Grasshopper programında mukarnas desenlerinin dijital ortama aktarılması ve parametrik hesaplama süreci ele alınmıştır. Yöntemde öncelikle mukarnasın boyutu, şekli ve karmaşıklığı gibi tasarım parametreleri tasarımcı tarafından programda aktarılır. Bu girdiler her birinin şeklini ve boyutunu içermektedir. Böylece mukarnasın davranışını yönetecek algoritmalar ve denklemler oluşturulması sağlanır. Mimarlar ve tasarımcılar, geleneksel mukarnasları veya mimari unsurları dijital tasarımda parametrik girdi ve çıktılarla yeniden yorumlamak için Rhino-Grasshopper'ı kullanabilirler. Bu, farklı tasarım seçeneklerini hızlı ve kolay bir şekilde keşfetmelerine ve geleneksel tasarım yöntemleri kullanılarak elde edilmesi zor olan estetiğe dayanan benzersiz, karmaşık desenler oluşturmalarına olanak tanır.

## РЕЗЮМЕ

### **Реинтерпретация Мукарнаса как традиционного архитектурного элемента в цифровом дизайне с помощью программы Rhino-Grasshopper**

**Ясемин ТУРАН**

**Анкарский университет Йылдырыма Беязыга, Турция**

**Ихсан ТОКТАШ**

**Анкарский университет Йылдырыма Беязыга, Турция**

Мукарнас – это традиционные архитектурные элементы, обычно встречающиеся в Исламской архитектуре. Эти трехмерные декоративные элементы, используемые для придания визуального интереса и глубины зданиям и другим сооружениям, широко использовались в украшениях куполов и сводов. Мукарны, это трехмерные сложные геометрические фигуры, созданные путем наложения Исламских геометрических узоров друг на друга. Мукарнас — это трудоемкая и трудоемкая работа, требующая традиционных методов, таких как резьба и лепка. В настоящее время стало возможным быстро и легко создавать сложные мукарны, используя различные алгоритмы и методы параметрического проектирования в цифровой среде, а также создавать такие инструменты проектирования, как Rhino-Grasshopper — от базовых моделей до новых переменных моделей.

В этом научном исследовании обсуждался перенос узоров мукарна на цифровые носители и процесс параметрического расчета в программе Rhino-Grasshopper. В методе, прежде всего, параметры дизайна, такие как размер, форма и сложность мукарн, переносятся дизайнером в программу. Эти записи включают форму и размер каждого.

Таким образом создаются алгоритмы и уравнения, которые будут управлять поведением мукарн. Архитекторы и дизайнеры могут использовать Rhino-Grasshopper, чтобы по-новому интерпретировать традиционные мукарны или архитектурные элементы в цифровом дизайне с параметрическими входами и выходами.

Это позволяет им быстро и легко исследовать различные варианты дизайна и создавать уникальные, сложные узоры, основанные на эстетике, которую трудно достичь с помощью традиционных методов дизайна.
