INTERACTIONS BETWEEN PRODUCTION MANAGEMENT TECHNIQUES, RENEWABLE ENERGY SOURCES AND ECONOMIC GROWTH IN TURKEY

Alp Par

Introduction

The problem of production and development economics is a general problem involving all sectors and business areas, social activities, production processes and relations. The problem of production and development economics is related to knowledge, culture, science, health, technical, education, engineering, production, technology, research development, economic development processes theory and implementation economies. Processes and business lines production and development economics problems theories, applied microeconomics techniques, initiatives; productivity, profitability, continuity, integrity, flexibility; developmentability, interchangeability criteria are investigated and analyzed.

Production economics, micro-economy production, production management processes related to technical research and implementation services, product applications are in line with the implementation. Investigates the production factors, supply and supply cost, demand, supply and demand balance, price balance, income, profit, value added, loss change principles and decision methods at sectors and firms level. Production economy is applied to research development, education, technical, technology, production,
development and health processes in specific sectors and business areas and is shaped by processes. In the direction of these ideas, information economics, education economics, energy economics, health economics, research economics, agricultural economics, production economics, business economics, transportation economics, growth and development economics, are based on the world economy and practices. Therefore, working model and function, production inputs, investment capital and efficiency, investment feasibility, long-term unit cost, unit second-hand price, capital stock, supply and demand future balances, production process profit-loss criteria, growth and sector problems and analysis and research methods. It is aimed at opening production and growth models, specific and strategic production priorities and forms of sectors. In the process, it is aimed to investigate and discuss the income, socioeconomic and welfare levels, social psychology, perception and entrepreneurial levels of people in the country, and the raising criteria for generating added value. Working in this direction is directed to the determination of deterministic, analytical and synthetic methods related to decision criteria of production and investment economics and evaluations of local and sector processes. Medium and long-term production tries to lay down the basic criteria, forms and effects. It tries to set the criteria for the determination of investment and production inputs medium and long-term significant marginal efficiency and profitability of the resources and the economic criteria of the investment's fixed investment, social capital and working capital inputs. The sermons of resources; tries to put forward the criteria of economic use without wastage.

Energy production techniques and the energy sector contribute to countries’ economy by producing surplus energy yields over and above the energy required to ensure those services. In addition, an energy sector that involves all of the energy that it produces to fuel its own processes is of little use to country. In fact, econometric energy models including Message, Markal considering just for gross production by the energy sector, P, net energy analysis takes into account whole energy flows among the energy sector and the economy as indicated in Figure: 1.
Figure 1: Energy and material flows among the energy sector and the main economy. Gilliland, 1975.

The Figure 1, above demonstrates the relationship between energy sector and some factor of production including labour & capital and most important parameters of economic growth such as labour and capital. The main interception point is production which is located as center of the figure above.

**Literature Review**

O’Callaghan and Probert (1977) states that production management is one significant catalyzer to improve production systems towards energy efficiency as it may be essential for successfully using energy efficiency developments. Kumar and Suresh (2006) express that production management and its operations has been recognised as a crucial factor in a country’s economic growth. Economic growth and production are directly proportional. Directing the population and capital to the appropriate investments channels will improve the production and production management techniques and ensure economic growth (Öztürk, Kalaycı, Korkmaz, 2017). Oakland and Sohal (1987) demonstrates that developed countries relies heavily more on its manufacturing capability to ensure a healthy economy which is one of the most crucial assets of production & operations managers.

The role of production system is so vital and indispensable to provide better economic growth and majority of studies have mentioned regarding the importance of that issue. Ghandoor (2013) concentrate more on the linkage among energy and the transportation sector, working out econometrical models and expressing that, specifically, Japan is one of the most prospering
countries in terms of managing energy resources effectively by using production economics. Japan, II. Despite the great defeat after World War II, it has become an economic power that can compete with the USA and it can be stated that production management and its models have an effective role regarding economic growth (Alkış & Temizkan, 2013: 75).

Turan (2018) found that the size of teamwork from Japanese management model dimensions demonstrated significant differences statistically according to gender and marital status. The difference between the other dimensions according to demographic characteristics is not statistically significant. In general, it is seen that Japanese management model has a high level of compliance with the Turkish automotive sector. Kalayci and Tekin discourses the role of banking sector on the dimension of production techniques and its channels in order to enhance economic growth.

Azad, Khan, Ahasan and Ahmed (2014) examines Australia’s storage and export (including renewable and non-renewable), energy production, consumption,. Their major goal is to analyze the prospect of renewable energy in Australia. They found that Australian economy will develop better if its undeveloped renewable energies can be used effectively for transporation sector and electricity generation. Christoffersen, Larsen and Togeby (2006) states that Denmark’s economy is energy-oriented, and a comparatively low fraction of energy used in the production process. Besides, energy is an integrated part of the strategic targets for the companies and primary as well as production processes and its management are integrated in the saving activities in Denmark.

**Methodology and Data Analysis**

The relationship between economic growth and renewable energy sources has been examined from 1960 to 2015 in order to reveal the role of production management techniques on energy production and its contribution to economic growth of Turkey. The data is derived from Worldbanks’ official website as 56 years which is more than 30 to make it parametrical test. The co-integration test is implemented to demonstrate the long-run relationship between economic growth and renewable energy sources. The one of the most significant indicator of economic growth is GDP (Gross domestic Product) and it is used as variable for time series analysis.
Table 1: ADF Unit Root Test at I(0) for GDP from 1960 to 2015 for Turkey

<table>
<thead>
<tr>
<th>Country</th>
<th>Variables</th>
<th>Series at I(0) t-stat/crit-val  %5/p-val</th>
<th>After converting from I(0) to I(1) t-stat/crit-val %5/p-val</th>
</tr>
</thead>
<tbody>
<tr>
<td>Turkey</td>
<td>GDP</td>
<td>0.7093 / -2.91 / 0.9913</td>
<td>-6.89 / -2.91 / 0.0000</td>
</tr>
<tr>
<td></td>
<td>Electricity production</td>
<td>-0.6245 / -2.91 / 0.9892</td>
<td>-11.39 / -2.91 / 0.0000</td>
</tr>
</tbody>
</table>

For both of GDP and electricity production are non-stationary at level I(0). For that reason, first difference are taken to test unit root problem. After converting the series from I(0) to I(0), they all become stationary. Thus, Johansen Co-integration test is implemented to comprehend long-term relationship between variables.

According to results of empirical findings of co-integration test, as long as increasing production management techniques on renewable energy management, it ensures economic growth. Majority of studies in academic literature have mentioned about the relationship between economic growth and energy production to put forward the lean production philosophy and its contribution to energy production and eventually to economic growth which is consistent with Kumar and Suresh’s (2006) opinions and their empirical findings.
Conclusion

Consequently, integration of energy efficiency in production management is so significant in order to provide stable economic growth. Particularly, effective energy management triggers energy efficiency in production management by reducing energy consumption and its costs which is necessary to integrate better management cognizance and systems. These new approaches should be improved in terms of production management techniques in collaboration of academia and industry partners to provide their applicability in manufacturing firms and to contribute the diffusion of management approaches for energy production.

Japanese production techniques, adaptation and implementation of Kaizen philosophy to the production process will play an important role in reducing the current account deficit, so as to increase productivity in the production process, both energy production and economic growth will be enhanced efficiently. One of the most important reasons of the adaptation of the Japanese production model to the Turkish type production system is that the points related to the production, rather than social or social phenomena such as cultural differences, are more prominent. Similar approaches in the academic literature can be seen in Taylor or Fordist type production systems. However, one of the differentiating aspects of the Japanese type production system is that it does not refer to other methods such as internalizing and externalizing the production management and the course, rather than thinking of people as a machine.

Thus, a system that focuses solely on production functions, with the highest efficiency in production and lowest cost, is much more likely to survive in competition and in today's conjuncture. Turkey on the development of the automotive and energy sectors also be said that the role of this model.

Изучение различий между экономическим ростом в Турции, методами управления производством и возобновляемыми энергетическими ресурсами

Алп Пар

Уровень экономического роста и управления производством - это ситуация, когда страны ведут борьбу. Потому что экономическое развитие усиливается благодаря справедливому распределению доходов. Социальное благополучие - счастливая жизнь для людей. Одной из важнейших частей экономического роста является энергия. Независимо от предмета производства энергия на производственных объектах важна как для фиксированных, так и для переменных затрат.

Основной целью этой статьи является определение взаимосвязи между возобновляемыми источниками экономического роста и производством электроэнергии для Турции с 1960 по 2015 год. Для параметра теста интеграции в качестве примера был использован 56. Информация была получена с официального сайта Всемирного банка. По результатам этого исследования существует долгосрочная постоянная связь между переменными. Таким образом, роль методов управления производством в производстве энергии была эмпирически доказана как вклад в экономический рост в Турции.

Ключевые слова: управление производством, экономический рост, возобновляемые источники энергии, Турция, социальное обеспечение
